PREDICTION

TIME SERIES

Run a simple prediction

Track the corals time series (set to 4, but it could be adjusted)

Prediction Page

Prediction Page

Please upload your corals.

Browse... No file selected.

UPLOAD

First, click here to upload
transect or coral colony
ortho

Then, click here to run the
prediction. This operation can
take between 1 to 3 mins based
on image size.

Prediction Page output

Prediction Page

Please upload your corals.

Browse... AM10.png

UPLOAD

After the model finishes the segmentation, the results will be displayed automatically.

Time Series Page

Please upload your time series.

After the model finishes the segmentation, the results will be displayed automatically.

Time Series Page Output

Time Series Page

Please upload your time series.

Afterward, the results are displayed by our model. The next step is to select the coral we want to track over time by clicking on it.

In real time, size is calculated and displayed according to reference.

PRESS RELEASE

FOR IMMEDIATE RELEASE

University of Guam and University of Miami Partnership Use Guam Datasets to Monitor Coral Reef Changes using new NeMO-Net & PICOGRAM Tools

Beneath the surface of the Earth's oceans, coral reefs are undergoing significant changes. Transformations like coral bleaching are visible to the naked eye, while others like coral growth and mortality occur at the centimeter scale and would be much more difficult to measure over time. As these biodiverse and economically vital marine ecosystems face ongoing threats such as rising sea temperatures and human interference, researchers from the University of Guam (UOG) and the University of Miami's Rosenstiel School are working together to explore various solutions that could advance coral reef monitoring and mapping through machine learning tools.

One collaboration is the *Prediction of Individual Coral Growth, Recruitment, and Mortality* (PICOGRAM) program, a computer-based tool in development by NASA & NOAA that uses machine learning to track coral colony size over extended time periods, supported by NASA's Ecological Forecasting Program and led by PI Prof. Sam Purkis at the University of Miami in partnership with NOAA.

UNSUPERVISED IMAGE SEGMENTATION BY BACK-PROPAGATION

A new approach with NeMO-Net CNN

After applying SLIC (Simple Linear Iterative Clustering) segmentation and setting compactness, the algorithm uses a CNN to extract feature representations directly from the input image without labeled data.

The CNN then assigns initial labels to pixels by selecting the highest activation across its feature maps, creating an initial segmentation map. This leverages the CNN's ability to learn patterns in an unsupervised manner, providing a foundation for iterative label refinement in subsequent steps.

Sample SLIC segmentation
