# Results and forthcoming products

## Part 1: Preliminary results from foliar dry spectral data

- Dry spectral predicted traits have patterns showing strong taxonomic affiliations between and within major plant families
- Certain traits are indicative of certain lineages
- Part 2: Anticipated ground data products

# How do we get from flights to trait maps?

A lot of lab/field  
spectral  
measurements

# Why measure foliar spectra?

What is community-weighted mean value for a pixel?

# Why measure foliar spectra?

Plot Nitrogen = (Spp. 1 cover \* Spp. 1 Nitrogen) + (Spp. 1 cover \* Spp. 1 Nitrogen) + (Spp. 1 cover \* Spp. 1 Nitrogen)

# Why measure foliar spectra?

# Why measure foliar spectra?

Much cheaper to collect  
spectra on these leaves  
and predict trait values

# Cost efficient to collect spectra on these leaves and predict trait values

We may only need to measure N for one of the species to validate our model

# We measure both fresh and dry spectroscopy from plants to get different sets of traits

# Dry vs. fresh spectra (*Protea repens*)

# Ordination of traits predicted from dry spectra high separation between Cape plant families

Ordination also shows high separation **between genera**  
(Proteaceae)

Plant Family

Indicator Value Analysis Heatmap

Cellulose  
indicative of  
Grasses,  
Sedges, Irises,  
and Restios

Plant Family

Nitrogen  
indicative of  
Fabaceae and  
lineages found  
outside of  
Fynbos

Plant Family

The Proteaceae  
“sugar bushes”  
indicated by  
sugar content
