

INTRODUCTION

Animal locations (n)
1 100 10000

During 2020, many countries worldwide went into lockdown to control the spread of COVID-19. While brought under the most unfortunate of circumstances, this period of unprecedented reduced human mobility, - coined the anthropause - can provide unique insights into human-wildlife interactions [1]

We quantify how terrestrial birds and mammals altered their (I) space use across the USA in response to human infrastructure and mobility during 2019-2020.

We (II) introduce the concept of an anthropause repository to lay future foundations for human-wildlife studies during current and future anthropauses

MATERIALS & METHODS

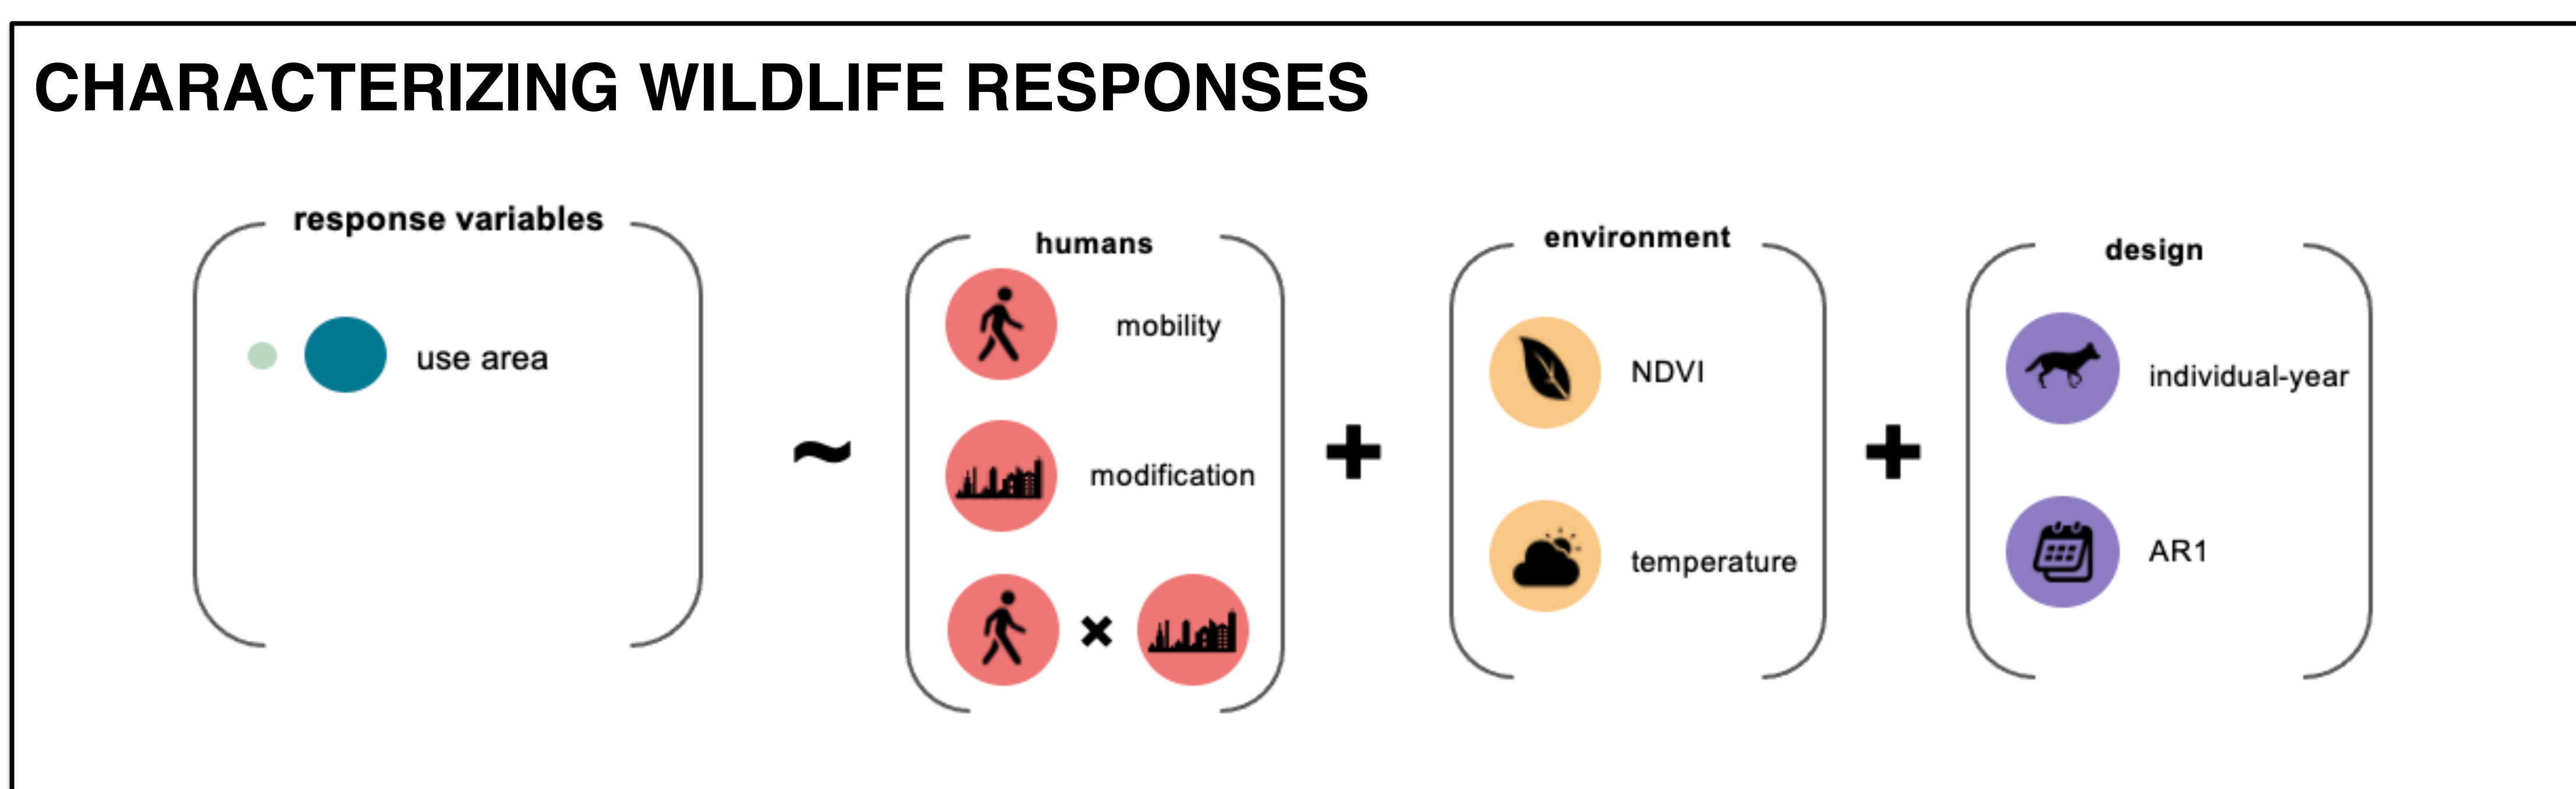

Animal movement data:
Data mobilization by the COVID-19 Biologging Initiative ~12 million GPS locations, 4000+ individuals across terrestrial birds & mammals

Human mobility (Dynamic, SafeGraph) [2] & infrastructure (Static, Human Modification Layer)

Environmental variables: NDVI (MODIS), Temperature (DayMet), Precipitation (CHIRPS)

Analysis:
Weekly dynamic Brownian bridge movement model [3]

Model space use responses as a function of anthropogenic and environmental predictors

ANTHROPAUSE READINESS & NEXT STEPS

The 2nd ACM SIGSPATIAL International Workshop on Animal Movement Ecology and Human Mobility
Seattle, Washington, USA - 1 November 2022

We plan to make studies discoverable, and if data owners wish, downloadable, to ensure future use of this unique dataset to facilitate future studies and increase our anthropause readiness [5]

Efforts will mirror NASA supported animal movement arctic archive [6] with the motivation of creating a living repository

We are supporting other global COVID-19 Biologging Initiative with conceptual, methodological and remote sensing support

I am co-organizing a working group on bringing human geographers and movement ecologists together to dynamically study human wildlife interactions

Started writing of manuscripts with co-authors Oliver & Yanco [7, 8]: COVID-19 pandemic reveals generality and idiosyncrasy in wildlife responses to human activity, 'Towards a dynamic-human footprint for assessing human-wildlife interactions'

Niche breath calculations will build upon developed methodology

Multispecies trait models to follow

RESULTS

CASE STUDY: COUGAR

Puma concolor

Cougar space use declined with increasing human mobility, infrastructure & their interaction

Moved closer to settlements during the anthropause [sensu 4]

Human Mobility vs Week of the year

Year: 2019 (blue), 2020 (red)

Human modification: 0.25, 0.50, 0.75

Data from Chris Wilmers

CASE STUDY: MULE DEER

Mixed responses

Year: 2019 (blue), 2020 (red)

Human modification: 0.070, 0.075, 0.080

Data from Tal Avgar

ANTHROPAUSE TYPOLOGY

Species	modification	mobility	interaction
Cougar (<i>Puma concolor</i>)	negative	negative	low
Wolf (<i>Canis lupus</i>)	negative	non-significant	low
Bobcat (<i>Lynx rufus</i>)	non-significant	non-significant	low
Black bear (<i>Ursus americanus</i>)	non-significant	non-significant	low
Moose (<i>Alces alces</i>)	non-significant	negative	low
Pronghorn (<i>Antilocapra americana</i>)	negative	negative	low
Elk (<i>Cervus elaphus</i>)	non-significant	non-significant	low
Mule deer (<i>Odocoileus hemionus</i>)	negative	negative	low
White-tailed deer (<i>Odocoileus virginianus</i>)	negative	non-significant	low
Bighorn sheep (<i>Ovis canadensis</i>)	positive	positive	high

LEGEND

relationship: negative (red down arrow), positive (yellow up arrow), non-significant (grey circle)

modification: low (light purple), high (dark purple)

space use & niche breadth vs mobility: low (shallow slope), high (steep slope)

CONCLUSION

Idiosyncratic responses of terrestrial mammals to static infrastructure and dynamic human mobility

Wildlife responds differently to the build environment and the movement of humans

Anthropause typology may reveal general drivers across species life histories, diet breath, etc.

Developed cyberinfrastructure and scalable methodology paves the wave for large scale comparative movement ecology
